## Milestone 2 Report

Due to convenient of store data, we decided to keep one webpage instead of two pages which is "EasyAttendance.html". Original thought is when professor finish generates class form and press button, the webpage, "ClassTable.html", will show new webpage and professor can add name in the form. In this milestone, we trying to merge two webpages. After professor press the button, "Create Class", the student name class will show bottom in the same webpage. Till now, we can successful extract data from the form on the webpage and store data into csv file which is a kind of plain text file storing table data (Numbers and texts). However, we still cannot convert information from csv file into html webpage.

Our milestone progress is not bad, but we are little bit late of the process. Next step, we will create a random generate number by using JavaScript. After create student version, student can get the random generated number to login and take attendance. Then student version can send data to teacher version.

The challenge part is that we cannot use JavaScript to extract out date directly and we have to use button add column and row. If we not press button, the form will not reveal comprehensively.
